

Customer Segmentation for Promotional Campaign Strategy

➤ **Cleaning**

➤ **EDA**

➤ **MODEL – CLUSTERING**

➤ **RESULTS**

Cleaning Process

- Dropped columns that had the same information across the board
- Dropped Nan values
- Got rid of irregular registrations in the Marital Status column
- Dropped outliers found in the Income column
- Processed categorical values in order to make them usable in the model
- Processed registrations that contained dates to make them usable in the model

Exploratory Data Analysis Insights

The Amount of money spent on different product categories is highly correlated to the annual Income of the customer

Correlation Heatmap

Clustering using K-means

Silhouette score: a metric used to measure how well-defined the clusters are.

High silhouette score = Good

Low silhouette score = Bad

Two Clustering Paths

1. After Scaling our data
2. Without Scaling our data

1. Clustering on Scaled data

Clusters = 3

Silhouette score : 0.014 (low)

Clusters = 4

Silhouette score : 0.02 (low)

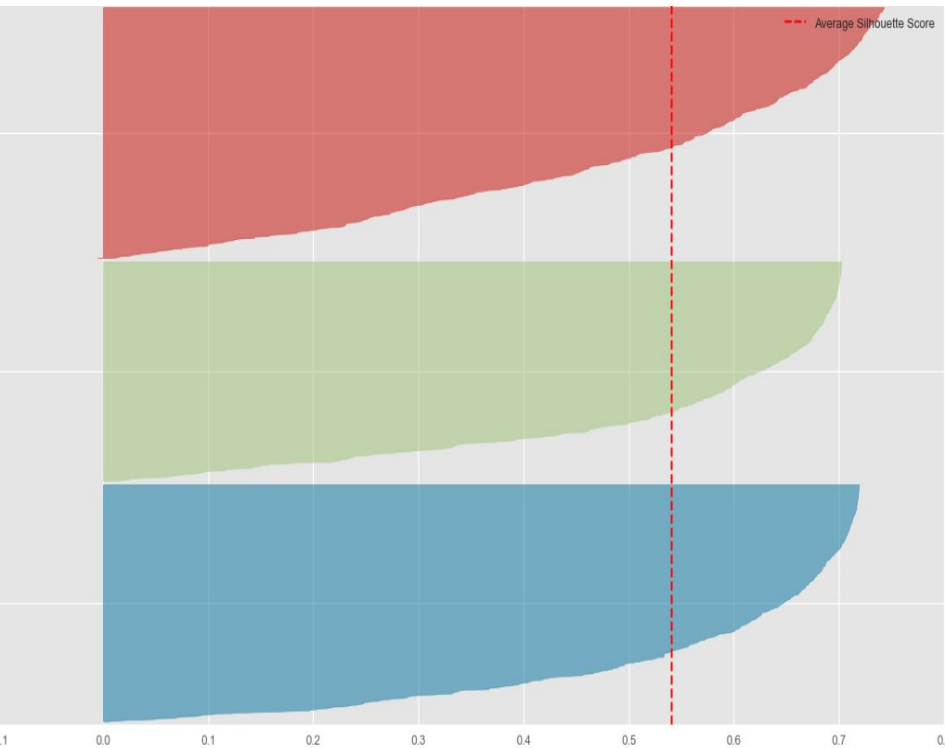

**Clustering on Scaled data does
not create meaningful results**

2. Clustering Without Scaling

Clusters = 3

Silhouette score : 0.54 (high)

Clusters = 4

Silhouette score: 0.52 (high)

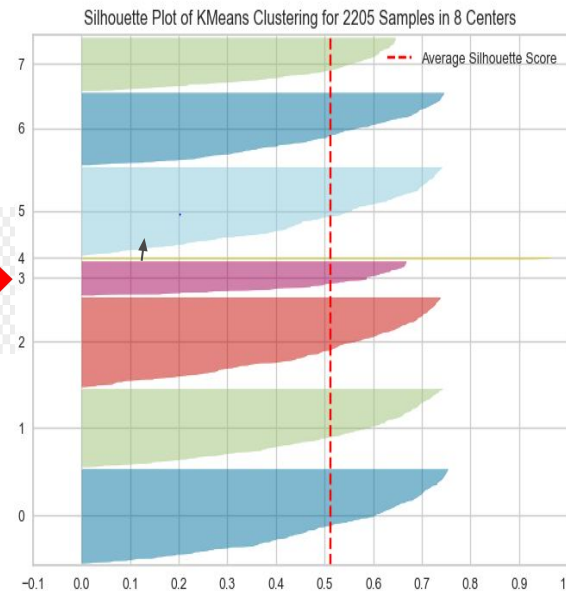

Choosing Number of Clusters

Any choice between 2-6 clusters is acceptable.

More than 7 clusters creates imbalances that we do not want

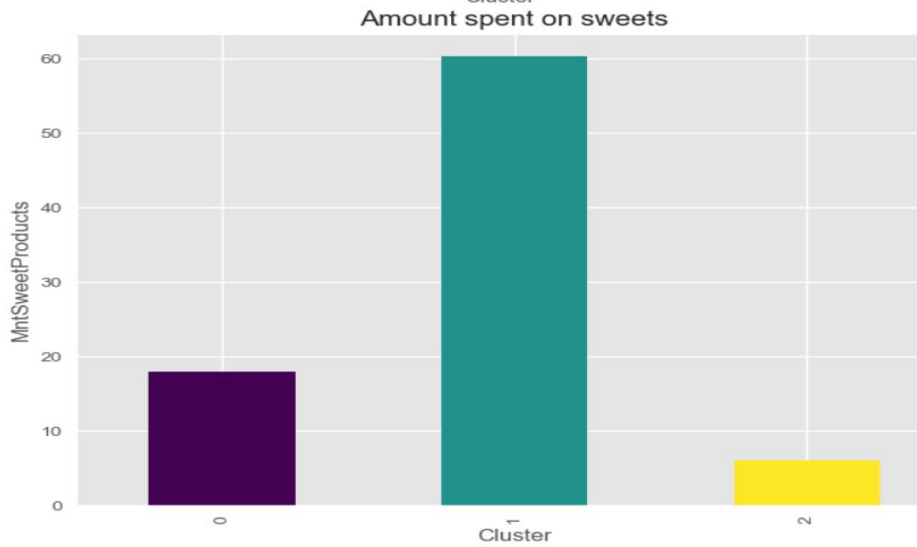

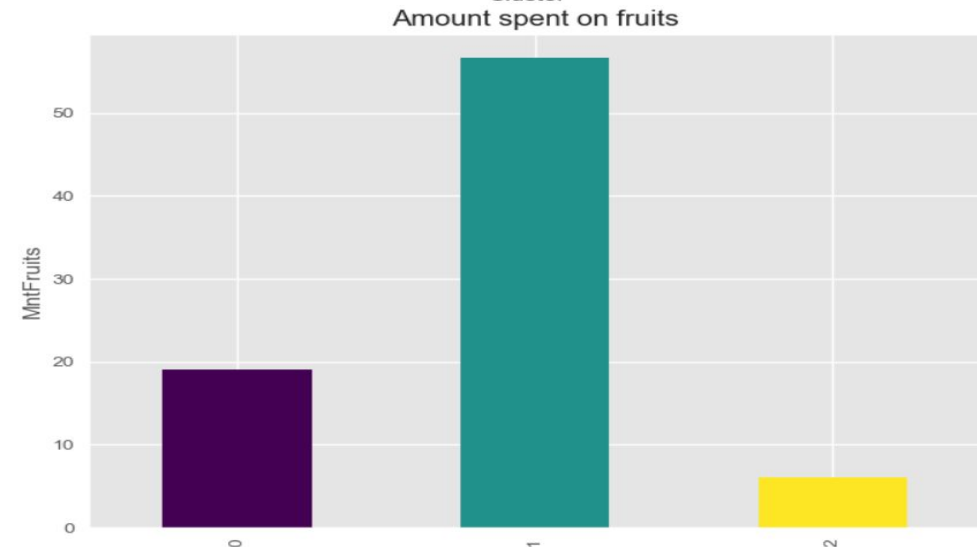

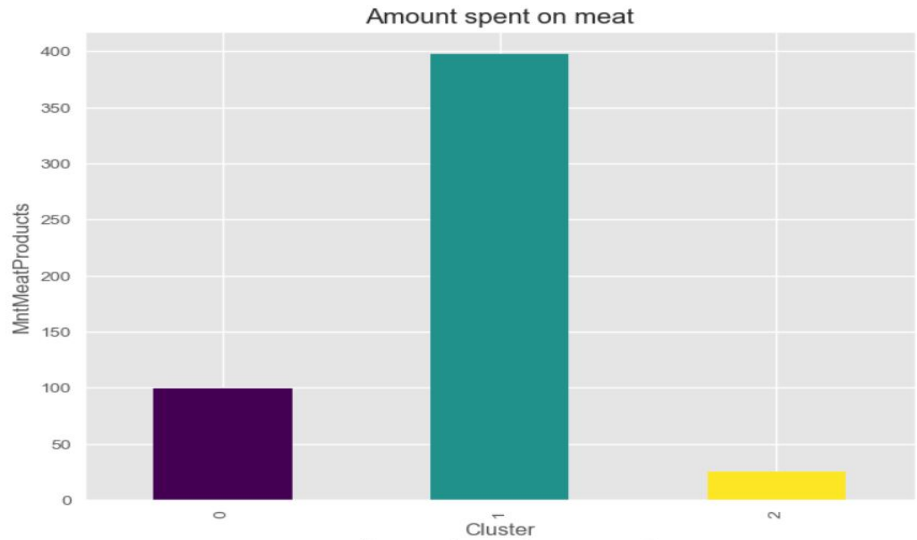

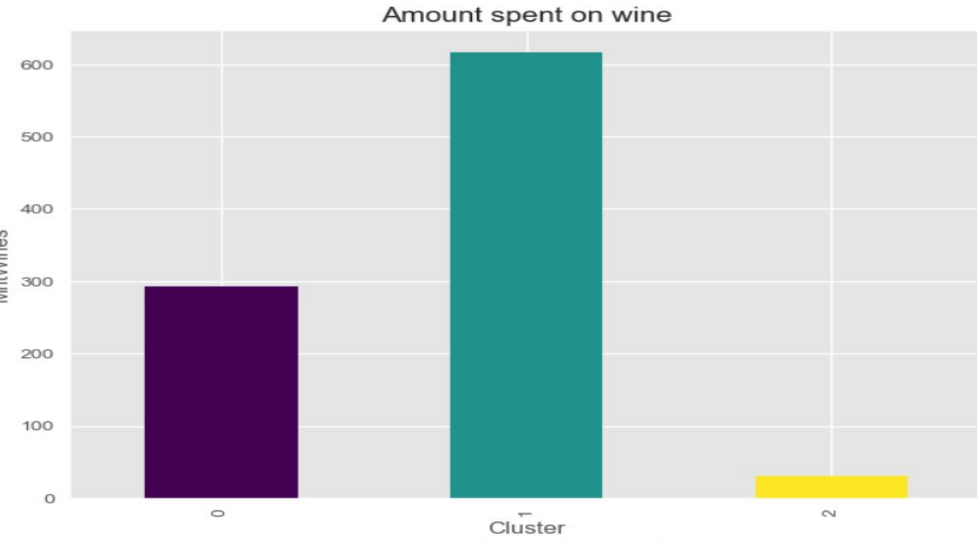

Explaining Customer Clusters

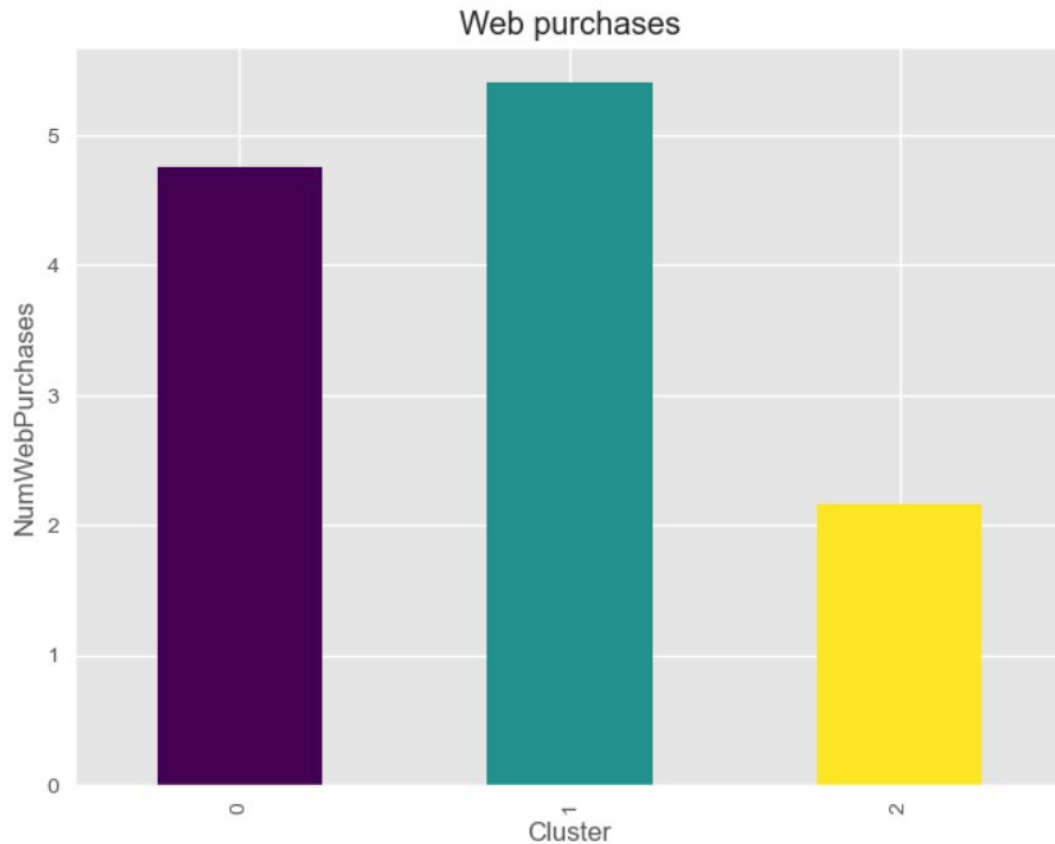

- The algorithm splits customers into different clusters based on their income
- Customers with Higher income spent more but buy similar amounts of products.
 - This means that they tend to make more expensive purchases
- Customers with Higher income buy less products on discounts

Customer Segmentation 3 classes

Customers with Higher income spent more but make similar amount of purchases

Customers with higher income do not take into consideration discounts

Closing Thoughts

- The number of clusters should be decided according to the number of different promotional campaigns the store is willing to run, and they should not exceed 6
- To lessen the impact of customer income in the clustering process we will need more data on the purchasing behavior of each customer (e.g. type of products bought, purchasing frequency)
